Telugu FastSpeech 2 — Recovery Experiment

This addendum documents the recovery training and final inference artifacts produced for the Telugu FastSpeech 2 experiment.

Training procedure

Training resumed from the original step-300 model weights. A fresh AdamW optimizer was initialized and 300 optimizer updates were verified. Recovery checkpoints were saved at steps 400, 500 and 600.

Corrected validation audit

Checkpoint	Corrected validation total loss
400	4.646829
500	4.301743
600	3.483655

Inference outputs

The recovered step-600 model generated five Telugu audio files: T1, T2a, T2b, T3 and T4. For each sentence, duration, pitch and energy prediction plots and numerical prediction files were saved. The universal HiFi-GAN vocoder was used for waveform generation.

Reproducibility and interpretation

The validation audit used the same 24 validation samples for each checkpoint and recorded the total loss directly. The reported validation values should not be confused with the earlier incorrectly summed validation metrics. The Telugu preprocessing and romanized character-level representation should be described when interpreting model quality.
